

# Charm meson production in 200 GeV p+p and Au+Au collisions at STAR

6th HADES School + 23rd Indian-Summer School of Physics

PHYSICS @ FAIR

David Tlusty

NPI ASCR, CTU Prague  
for STAR collaboration

# QCD phase diagram and RHIC

- How was the Universe created
- What are properties of strong interaction
- Search for and characterize the new state of matter – Quark Gluon Plasma

RHIC is an **intersecting storage** ring and **particle accelerator**. Two independent rings each 3.834 km circumference. **Can collide** any nuclear species on any other.

**Max Energy:**  $\sqrt{s_{NN}} \approx (Z/A) \cdot 500 \text{ GeV}$

# Why to study heavy quarks

knowledge on total charm production cross sections from p+p to central heavy ion collisions is critical to understand both open charm and charmonium production mechanisms in the QGP medium at RHIC

- large heavy quark mass is not easily modified by the QCD medium
- heavy quarks expected to be created from the initial hard scatterings
- Study properties of the hot and dense medium at the early stage of heavy-ion collisions.
- Charm collectivity => Light flavor thermalization.
- Test pQCD at RHIC.

# How to measure charm quarks

- direct clean identification (invariant mass peak)
    - At RHIC only STAR can provide this
  - large combinatorial background
  - need handle on decay vertex
- ⇒ requires high resolution silicon vertex detectors

# The STAR detector

Solenoidal **T**racker **A**t **R**HIC :  $-1 < \eta < 1, 0 < \phi < 2\pi$

➤ VPD EW coincidence: minimum bias trigger, TOF start time

➤ TPC : PID, tracking

➤ TOF : PID ( $\beta$ , **time resolution = 110 ps**)

➤ BEMC : remove pile-up tracks,  $E_T$  triggers

➤ TPC  $dE/dx$  vs  $p$  : pions PID

➤ TOF  $1/\beta$  vs  $p$  : kaons PID

Year 2009 72% of full TOF

Year 2010 100% of full TOF

# Pile-up removal

- pp collisions peak luminosity  
 $L_{\text{peak}} = 5 \cdot 10^{31} \text{ cm}^{-2}\text{s}^{-1}$  in year 2009.
- EventRate =  $L_{\text{peak}} \cdot \sigma^{\text{NSD}}(30 \text{ mb}) = 1.5 \text{ MHz}$
- TPC readout  $\sim 80 \mu\text{s} \Rightarrow$  TPC sees tracks from 120 collisions. Pile-ups are removed by
  - $|V_{\text{pdVz}} - V_{\text{tpcVz}}| < 6\text{cm}$  cut
  - TPC PPV reconstruction algorithm

# Particle Identification

From  $|\vec{p}| = m\gamma\beta$ ,  $\beta = L/ct$  one can calculate mass from

$$m_{\text{track}}^2 = p^2 \left( \frac{t^2 c^2}{L^2} - 1 \right) \quad m[\text{GeV}/c^2], p[\text{GeV}/c]$$

# D0 signal in p+p 200 GeV

$$D^0(\bar{D}^0) \rightarrow K^\mp \pi^\pm$$

B.R. = 3.89%

p+p minimum bias 105 M

4- $\sigma$  signal observed.

Different methods reproduce combinatorial background.

Consistent results from two background methods.

PDG mass =  $1864.5 \pm 0.4$  MeV

# D\* signal in p+p 200 GeV

Minimum bias events in p+p 200 GeV collisions.

Two methods to reconstruct combinatorial background: wrong sign and side band.

8-σ signal observed.

B.I.~Abelev, *et al.*, *PRD* 79 (2009) 112006.

Background combinations:

**Wrong sign:**

$D^0$  and  $\pi^-$ ,  $\bar{D}^0$  and  $\pi^+$

**Side band:**

$1.72 < M(K\pi) < 1.80$  or

$1.92 < M(K\pi) < 2.0 \text{ GeV}/c^2$

# $D^0$ and $D^*$ $p_T$ spectra in p+p 200 GeV

$D^0$  scaled by  $N_{D^0}/N_{cc} = 0.56^{[1]}$

$D^*$  scaled by  $N_{D^*}/N_{cc} = 0.22^{[1]}$

Consistent with FONLL<sup>[2]</sup>  
upper limit.

$X_{\text{sec}} = dN/dy|_{y=0}^{cc} * F * \sigma_{pp}$

$F = 4.7 \pm 0.7$  scale to full  
rapidity.

$\sigma_{pp}(\text{NSD}) = 30 \text{ mb}$

The charm cross section  
at mid-rapidity is:

$202 \pm 56 \text{ (stat.)} \pm 40$   
 $\text{(sys.)} \pm 20 \text{ (norm.) } \mu\text{b}$

The charm total cross  
section is extracted as:

$949 \pm 263 \text{ (stat.)} \pm 253$   
 $\text{(sys.) } \mu\text{b}$

[1] C. Amsler et al. (Particle Data Group), PLB 667 (2008) 1.

[2] Fixed-Order Next-to-Leading Logarithm: M. Cacciari, PRL 95 (2005) 122001.

# D<sup>0</sup> signal in Au+Au 200 GeV

Minimum bias 0-80% 280M Au+Au 200 GeV events.

8- $\sigma$  signal observed.

Mass =  $1863 \pm 2$  MeV (PDG value is  $1864.5 \pm 0.4$  MeV)

Width =  $12 \pm 2$  MeV

# Charm cross section vs $N_{\text{bin}}$

All of the measurements are consistent.

Year 2003 d+Au :  $D^0 + e$

Year 2009 p+p :  $D^0 + D^*$

Year 2010 Au+Au:  $D^0$

Charm cross section in Au+Au 200 GeV:

Mid-rapidity:

$186 \pm 22 \text{ (stat.)} \pm 30 \text{ (sys.)} \pm 18 \text{ (norm.)} \mu b$

Total cross section:

$876 \pm 103 \text{ (stat.)} \pm 211 \text{ (sys.)} \mu b$

[1] FONLL: M. Cacciari, PRL 95 (2005) 122001.

[2] NLO: R. Vogt, Eur.Phys.J.ST 155 (2008) 213

[3] PHENIX e: A. Adare, et al., PRL 97 (2006) 252002.

Charm cross section follows number of binary collisions scaling =>

**Charm quark produced at early stage of collisions.**

# $D^0 R_{AA}$ vs $p_T$

$$R_{AA}(p_T) = \frac{\frac{d\sigma_{c\bar{c}}^{Au+Au}}{dp_T dy}}{N_{bin}^{Au+Au} \frac{d\sigma_{c\bar{c}}^{p+p}}{dp_T dy}}$$

Below 3 GeV/c,  $R_{AA}$  consistent with unity =>

Consistent with  $D^0$  yield  $N_{bin}$  scaling behavior.

Blast-wave describes data with

$\langle \beta_T \rangle = 0.21 \pm 0.20$  (small, not sensitive).

$T = 287 \pm 106$  MeV

$T > T_h \sim 100$  MeV, larger than light hadrons

# Summary

---

- ◆  $D^0$  and  $D^*$  are measured in p+p 200 GeV up to 6 GeV/c – the first measurement at STAR
- ◆  $D^0$  are measured in Au+Au 200 GeV up to 5 GeV/c.
- ◆ 1) Charm cross sections at mid-rapidity follow number of binary collisions scaling  
2)  $R_{AA}$  is consistent with unity.

Indicate charm is produced at early stage of the collisions.

- ◆ The charm cross section in mid-rapidity is measured to be

p+p:  $202 \pm 56$  (stat.)  $\pm 40$  (sys.)  $\pm 20$  (norm.)  $\mu\text{b}$

Au+Au:  $186 \pm 22$  (stat.)  $\pm 30$  (sys.)  $\pm 18$  (norm.)  $\mu\text{b}$

- ◆ Blast-wave fit favors larger temperature and smaller velocity compared to light hadrons, which could indicate that  $D^0$  decoupled earlier from the medium than light hadrons.

# Why to measure D mesons?

Known limitations in semi-leptonic channel.

- 1) Kinematics smearing due to decay.
- 2) Suffering from charm and bottom contribution.

Both FONLL calculation and experimental data from electron channel are with large uncertainties.

Direct measurement of D meson provides clean information of charm quark.

- $v_2$  : thermalization

The figure consists of two panels sharing a common x-axis: Transverse Momentum  $p_T$  (GeV/c) ranging from 0 to 10.

**Top Panel:** Anisotropy Parameter  $v_2$  (%) vs  $p_T$ . The y-axis ranges from 0 to 25. The plot shows data for 200 GeV Au+Au collisions at RHIC, with  $D^0$  500M minimum bias events and  $|y| < 0.5$ . The legend indicates:
 

- Hydro (blue dotted line)
- charged hadrons (purple solid line)
- $v_2(c) = v_2(q)$  (red dashed line with circles)
- $v_2(c) = 0$  (green dashed line with triangles)

 The data points with error bars show a clear  $p_T$  dependence, with the charged hadron  $v_2$  being higher than the  $v_2(c) = 0$  case at low  $p_T$ .

**Bottom Panel:** Centrality scaling  $R_{CP}$  vs  $p_T$ . The y-axis ranges from 0.1 to 2.0. The plot shows the centrality scaling  $R_{CP}$  for charged hadrons. The legend indicates:
 

- Charged hadron  $R_{CP}$  (blue dashed line with circles)
- Expected errors on  $D^0 R_{CP}$  (open circles)

 Two horizontal shaded regions indicate the expected scaling:
 

- $N_{part}$  scaling (green shaded region,  $R_{CP} \approx 0.35$ )
- $N_{bin}$  scaling (orange shaded region,  $R_{CP} \approx 1.0$ )

 The data points show a transition from  $N_{part}$  scaling at low  $p_T$  to  $N_{bin}$  scaling at high  $p_T$ .

# Systematic error study

- 1) Raw Counts – Difference between methods
- 2) nFitPoints - difference between  
MC(nFitPts>25)/MC(nFitPts>15) and  
Data(nFitPts>25)/Data(nFitPts>15)
- 3) DCA - difference between MC(dca<1)/MC(dca<2) and  
Data(dca<1)/Data(dca<2)

# Charm cross section vs $\sqrt{s_{NN}}$

Most precise measurement so far, provide constraint for theories.
