University of Florida

**Definition.** If  $C$  is a class of relational structures and  $E$  is an analytic equivalence relation on a Polish space  $X$ , say that  $E$  is *C-structurable* if there is an analytic structure  $M$  on  $X$  such that for every equivalence class  $A \subset X$ ,  $M \upharpoonright A \in C$ .

**Example.**  $E$  is *treeable* if there is a analytic graph  $H$  on  $X$  such that for every equivalence class  $A$  of  $E$ ,  $H \upharpoonright A$  is acyclic and connected.

**Theorem.** If  $E$  is a treeable equivalence relation on  $X$  and  $F$  is an orbit equivalence relation of a turbulent group action on  $Y$ , then every Borel homomorphism from  $E$  to  $F$  stabilizes on a comeager set.

**Explanation.** If  $h : X \rightarrow Y$  is a Borel function such that  $x_0 E x_1$  implies  $h(x_0) F h(x_1)$ , then there is a single  $F$ -equivalence class with a comeager preimage.

**Turbulence characterization.** Suppose that a Polish group  $G$  acts on a Polish space  $Y$  with dense and meager orbits. The following are equivalent:

- the action is generically turbulent;
- $P_G \times P_Y \Vdash V[\dot{y}] \cap V[\dot{g} \cdot \dot{y}] = V$ .

**Improvement.** Let  $G$  act on  $Y$  in a generically turbulent way, inducing the orbit equivalence relation  $F$ . In some forcing extension there are points  $y_i \in Y$  for  $i \in \omega$  such that

1. the points are separately Cohen-generic over  $V$ ;
2. they are pairwise  $F$ -equivalent;
3. for every set  $a \subset \omega$ ,  $V[y_i : i \in a] \cap V[y_i : i \notin a] = V$ .

**Terminology.** Such a set of points is *independent*.

**Proof of Theorem.** Let  $E$  be a treeable equivalence relation on Polish  $X$ , as witnessed by an analytic graph  $H$ . Let  $F$  be the orbit equivalence of a generically turbulent action on  $Y$ . Let  $h : X \rightarrow Y$  be a Borel homomorphism from  $F$  to  $E$ .

Let  $y_i$  for  $i \in 4$  be independent generic points in the space  $Y$ . Then  $h(y_i)$  for  $i \in 4$  are  $E$ -related points in  $X$ , so they are in the same connected component of the graph  $H$ . The unique shortest paths between  $h(y_0)$  and  $h(y_1)$ , and between  $h(y_2)$  and  $h(y_3)$  must intersect. The point  $x$  in the intersection belongs to  $V[y_0, y_1]$  and  $V[y_2, y_3]$ , so to  $V$ .

The preimage  $h^{-1}[x]_E$  is comeager in  $Y$ .

**Generalizations.** Same conclusion for  $\mathcal{C}$ -structurable equivalence relations where

- $\mathcal{C}$  is the class of connected graphs without a perfect clique as a minor;
- $\mathcal{C}$  is the class of connected abstract simplicial complexes which are finitewise contractible.
