The aim of the present in 23 vitro study was to evaluate the potential impact bisphenols A, B, S and F on the cell viability 24 and testosterone release in TM3 Leydig cell line. Mice Leydig cells were cultured in the 25 presence of different concentrations of bisphenols (0.04-50 μ g.ml⁻¹) during 24 h exposure. 26 Quantification of the cell viability was assessed using the metabolic activity assay, while the 27

level of testosterone in cell culture media was determined by enzyme-linked immunosorbent assay. Within the panel of substances under investigations, the higher experimental concentrations (10; 25 and 50 μ g.ml⁻¹) significantly (*P*<0.001) decreased Leydig cells viability, while the same doses of BPA and BPB also reduced testosterone production significantly (*P*<0.001). Taken together, the results of our study reported herein is a consistent whit the conclusion that higher experimental doses of bisphenols have a cytotoxic effect and could have a dose-dependent impact on testosterone production.

35

Key words: bisphenols, Leydig cells, viability, testosterone

37

Bisphenol A (BPA, 2,2-bis[4-hydroxyphenyl] propane) is one of the oldest and most 38 studied synthetic substance known as an endocrine disruptor (ED). About 70 % of BPA 39 40 production is used to produce polycarbonate plastics used in a variety of common products such as plastic packaging, cling film, epoxy resins, food cans and many others (Vandenberg et al. 41 42 2007). Many studies showed that BPA may definitely affect steroidogenic process through alterations in steroidogenic enzymes and transport proteins, including impairment of 43 spermatogenesis followed by reduced semen quality parameters (Ye et al. 2011; Hulak et al. 44 2013; Vitku et al. 2015). Due to many negative effects, toxicity and widespread exposure, use 45 of BPA has been banned in some consumer products such as reusable food or beverage 46 containers, infant formula containers and baby bottles (Eladak et al. 2015). Nowadays, there 47 are several analogues to BPA such as bisphenol S (BPS), bisphenol F (BPF) or bisphenol B 48 (BPB). According to the previous studies, a direct inhibition of bisphenol alternatives on 49 steroidogenesis or spermatogenesis, with irreversible changes in sperm morphology, Sertoli 50 51 cells activity and hormonal imbalance is extensively discussed (Cao et al. 2012; Liao and Kannan, 2013). In addition, many authors confirmed neurotoxicity, genotoxicity, reproductive 52

toxicity and strong endocrine disruptive activity (Alves *et al.* 2013; Rosenmai *et al.* 2014).
Nowadays, toxicological data are scarce and experimental studies evaluating the effects of
bisphenol analogues are unclear. Under these endpoints, we have decided to urgently
investigate the effects of BPA, BPB, BPS and BPF as well as their cellular toxicity and potential
impact on steroidogenesis *in vitro*.

The TM3 Leydig cell line (ATCC #CRL-1714; Manassas, VA, USA) were cultured in 58 Dulbecco's Modified Eagle's Medium/Nutrient Mixture (Ham's) F12 with HEPEs and 59 NaHCO₃ (DMEM/F12; Sigma Aldrich, St. Louis, USA) supplemented with 5 % horse serum 60 (HS; Gibco-Life Technologies, New Zealand), 2.5 % fetal bovine serum (FBS; BiochromAG, 61 Berlin, Germany), 2.5 mM L-glutamine (Sigma Aldrich, St. Louis, USA) and 1 % 62 penicillin/streptomycin solution (Sigma Aldrich, St. Louis, USA). The Leydig cells density was 63 adjusted to a final concentration of 4×10^3 cells/well and seeded in 96-well plate for 24 h. TM3 64 65 cells were maintained at 37 °C under a humidified atmosphere of 95 % air and 5 % CO₂. Afterwards, the medium was changed to include different concentrations of bisphenols A, B, S 66 and F (Sigma Aldrich, St. Louis, USA), starting from 0.04 to 50 µg.ml⁻¹ and the cells remained 67 cultured during the next 24 h. The applied concentrations range of bisphenols was selected 68 according to the results of our pilot range-finding experiments. The viability of exposed cells 69 was estimated using the MTT (3-4,5-dietyltiazol-2-yl)-2,5-diphenyltetratzolium bromide) 70 assay, which measured the reduction of a yellow tetrazolium salt to blue formazan in viable 71 cells (Mosmann, 1983). Formed formazan crystals were dissolved by isopropanol (p.a. 72 CentralChem, Bratislava, Slovak Republic) and read by an ELISA reader (Multiscan FC, 73 74 ThermoFisher Scientific, Vantaa, Finlad) at 570 nm against 620 nm wavelengths. Furthermore, the level of testosterone in cell culture media was determined by enzyme-linked immunosorbent 75 assay using ELISA kits purchased from Dialab (Testosterone Cat. #K00234; Austria). The 76 absorbance was measured at 450 nm by ELISA reader (Multiscan FC, ThermoFisher Scientific, 77

Vantaa, Finlad). The data were collected from four (n=4) independent experiments that were performed in triplicates and statistically analyzed using the GraphPad prism 5.0 (GraphPad Software Incorporated, San Diego California, USA). One-way analysis of variance (ANOVA) followed by Dunnett's test was used for statistical evaluations. Results were presented as means (\pm SEM) of Leydig cell viability % and testosterone % of control (untreated) and treated groups. Differences were compared for statistical significance at *P*<0.05.

As presented in Figure 1. the metabolic activity was significantly (P < 0.05; P < 0.001) 84 reduced at 10 (83.06±3.82%); 25 (85.63±3.36%) and 50 (52.79±6.05%) µg.ml⁻¹ of BPA. 85 Significant (P < 0.001) changes were also observed at the 25 ($66.08 \pm 2.34\%$) and 50 86 $(6.13\pm1.87\%)$ µg.ml⁻¹ of BPB, while 10 (84.81±0.70% and 83.46±6.22%); 25 (79.47±2.97%; 87 81.82±2.00%;) and 50 (61.30±4.14% and 46.31±0.77%) µg.ml⁻¹ of BPS and BPF decreased 88 Leydig cell viability significantly (P < 0.01; P < 0.001). The data suggest that the highest dose of 89 90 BPB (50 µg.ml-1) is extremely cytotoxic and the suppression may be increased by other bisphenols with time. The cytotoxic effects of bisphenols are shown at the photomicrograph 91 92 (Figure 2). BPA is one of the most well-studied endocrine disruptors (Kolatorova et al. 2017). 93 The ability to affect the cell viability of Leydig TM3 line in dose- and time- dependent manner of BPA in vitro was evaluated by Goncalves et al. (2018). The data showed that at 94 concentrations above 5 μ M (10 – 500 μ M) during 24 h exposure to BPA significantly inhibited 95 mitochondrial activity when compared to the control group. Nonetheless, the Leydig cell 96 viability did not decrease significantly after 48 h exposure to BPA at concentrations below 50 97 μM. In this case, higher experimental doses (100 - 500 μM) of BPA reduced mitochondrial 98 99 activity significantly. Roelofs et al. (2015) determined the metabolic activity of MA-10 cells after 48 h BPS and BPF exposure. The results showed non-cytotoxic effect at 0.01-30 µM of 100 101 BPS and 0.01-100 µM of BPF. The cytotoxic potential of BPS, BPB and BPF (10-300 µM) after 48 h incubation was investigated in the *in vitro* study by Russo *et al.* (2018). The biological 102

effect was evaluated using a well-established health and cancer cell lines (HeLa, MCF-7 and
3T3-L1). Moderate toxicity was observed for BPF and BPS on all cell lines, while BPB was
clearly toxic only for 3T3-L1 (mouse embryonic fibroblast) and MCF-7 (human breast cancer)
cells.

The results of our *in vitro* study indicate that experimental concentrations of BPA, BPB, 107 BPS and BPF (0.04-50 µg.ml⁻¹) may affect the testosterone production in mice TM3 Leydig 108 cells after 24 h exposure. A significant (P < 0.01; P < 0.001) reduction in hormone production 109 110 was recorded at 10 (69.66±8.32% and 59.93±1.96%); 25 (30.88±2.91%; 22.94±4.41%) and 50 $(20.54\pm3.51\%; 9.60\pm2.46\%)$ µg.ml⁻¹ of BPA and BPB compared to the controls. On the other 111 hand, BPS and BPF slightly reduced testosterone synthesis at the same concentrations, but not 112 significantly. We are convinced that the highest experimental dose of BPA and BPB have a 113 strong inhibitory potential evoked by decreasing in steroidogenic enzymes activity such as 3β-114 115 HSD or 17 β-HSD. A summary of testosterone production after 24 h treatment by bisphenols A, B, S and F in TM3 Leydig cells is presented in Table 1. Similar tendency was observed in 116 117 the previous study of Ok et al. (2017). They showed significant inhibition of testosterone and progesterone production by 100 µM of BPA treatment in comparison to the control group after 118 24 h exposition in TM3 cell line in vitro. Goncalves et al. (2018) study showed that the 119 concentrations 1, 10 and 100 µM of BPA are able to reduce testosterone production in TM3 120 Levdig cell line after 48 h incubation by approximately 22-39 % respectively, when compared 121 to the non-treated cells. Testosterone production in MA-10 cells after 48 h in vitro exposure to 122 experimental doses (0.01-100 µM) of BPF and BPS was evaluated by Roelofs et al. (2015). 123 Exposure to both of selected bisphenols in concentrations ranges of 0.01-30 µM for BPS, and 124 up to 100 µM for BPF showed that only BPF increased testosterone production, while BPS did 125 not affect this production in exposed cells. Suppression of testosterone synthesis may be 126 associated with inhibition of steroidogenic enzyme activity because there was a decrease in 127

steady state mRNA levels of the cytochrome P450 17α-hydroxylase/17,20 lyase, StAR and
Hsb3b1, although statistical significance was not reached (Akingbemi *et al.*, 2004; Eladak *et al.*, 2015)

In conclusion, our results showed that higher experimental concentrations from 10 to 50 μ g.ml⁻¹ of BPA, BPS and BPF as well as 25 or 50 μ g.ml⁻¹ of BPB, may adversely affect the viability of TM3 Leydig cells after 24 h *in vitro* cultivation. The results also suggest that all experimental doses (0.04 – 50 μ g.ml⁻¹) of bisphenols may affect testosterone release while the highest concentrations have inhibitive effects on steroid hormone production
